

Efabless Caravel “harness” SoC

Description:

The efabless Caravel chip is a ready-to-use test harness for creating designs with the Google/SkyWater 130nm open PDK. The Caravel harness comprises a small RISC-V microprocessor based on the simple 2-cycle PicoRV32 RISC-V core implementing the RV32IMC instruction set (see <http://riscv.org/>), a 32-bit wishbone bus, and an approximately 2.8 mm x 2.8 mm open area for the placement of user IP blocks.

Core:

The processor core is the PicoRV32 design (see <http://github.com/cliffordwolf/picorv32>). The full core description is available from the github site. The hardware implementation is the “large” variant, incorporating options IRQ, MUL, DIV, BARREL_SHIFTER, and COMPRESSED_ISA (16-bit instructions).

Core clock rate: (TBD) MHz maximum over all PVT conditions (likely around 50 MHz guaranteed)

Features:

Functions/features of the SoC include:

- 1 SPI flash controller
- 1 UART
- 1 SPI master
- 2 counter-timers
- 1 dedicated general-purpose input/output channel
- 27 shared general-purpose input/output channels
- 1k word (1024 bytes x 32 bits) on-board SRAM
- All-digital frequency-locked loop clock multiplier
- 128 bit logic analyzer
- Wishbone crossbar switch

License:

The Caravel chip is an open-source design, licensed under the terms of Apache 2.0.

Repository:

The complete Caravel chip design may be obtained from the git repository located at <https://github.com/efabless/caravel/>.

Process:

The efabless Caravel harness chip is fabricated in SkyWater 0.13µm CMOS technology, with process specifications and data at <https://github.com/google/skywater-pdk/>.

Version:

This document corresponds to version 1 of the Caravel processor (October 2020).

Documentation revision 0 (October 14, 2020)

Caravel harness die (3.2mm x 5.3mm)

General Purpose I/O

GPIO (pin E10)

The GPI pin is a single assignable general-purpose digital input or output that is available only to the management SoC and cannot be assigned to the user project area. On the test board provided with the completed user projects, this pin is used to enable the voltage regulators generating the user area power supplies.

The basic function of the GPIO is illustrated below. All writes to `reg_gpio_data` are registered. All reads from `reg_gpio_data` are immediate.

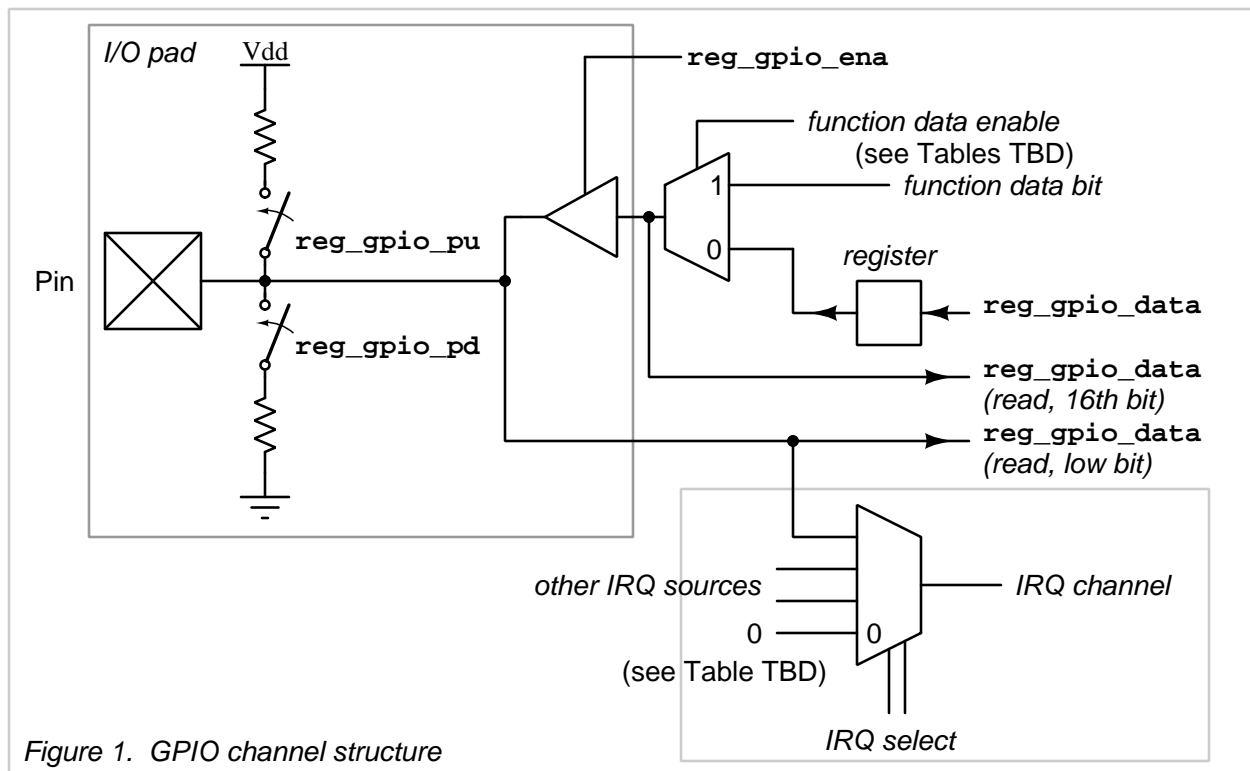

Figure 1. GPIO channel structure

GPIO memory address map:

C header name	address	description
<code>reg_gpio_data</code>	<code>0x21000000</code>	GPIO input/output (low bit) GPIO output readback (16th bit)
<code>reg_gpio_ena</code>	<code>0x21000004</code>	GPIO output enable (0 = output, 1 = input)
<code>reg_gpio_pu</code>	<code>0x21000008</code>	GPIO pullup enable (1 = pullup, 0 = none)
<code>reg_gpio_pd</code>	<code>0x2100000c</code>	GPIO pulldown enable (1 = pulldown, 0 = none)
<code>reg_pll_out_dest</code>	<code>0x2f000000</code>	PLL clock output destination (low bit)
<code>reg_trap_out_dest</code>	<code>0x2f000004</code>	Trap output destination (low bit)
<code>reg_irq7_source</code>	<code>0x2f000008</code>	IRQ 7 input source (low bit)

GPIO description, continued.

In the memory-mapped register descriptions below, each register is shown as 32 bits corresponding to the data bus width of the wishbone bus. Addresses, however, are in bytes. Depending on the instruction and data type, the entire 32-bit register can be read in one instruction, or one 16-bit word, or one 8-bit byte.

Table 1 **reg_gpio_data**

0x21000003				0x21000002				0x21000001				0x21000000				address																
GPIO output readback								GPIO input/output								value																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

Bits 0 to 15 and bits 16 to 31 correspond to GPIO channels 0 to 15, respectively.

Writing to the address low 16 bits always sets the registered value at the GPIO.

Writing to the address high 16 bits has no effect.

Reading from the address low 16 bits reads the value at the corresponding chip pin.

Reading from the address high 16 bits reads the value at the multiplexer output (see diagram).

Table 2 **reg_gpio_ena**

0x21000007								0x21000006								0x21000005								0x21000004								address
(undefined, reads zero)																GPIO output enable																value
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

Bit 0 corresponds to the GPIO channel enable.

Bit value 1 indicates an output channel; 0 indicates an input.

Table 3 **reg_gpio_pu**

0x2100000b								0x2100000a								0x21000009								0x21000008								address
(undefined, reads zero)																GPIO pin pull-up																value
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

Bit 0 corresponds to the GPIO channel pull-up state.

Bit value 1 indicates pullup is active; 0 indicates pullup inactive.

Table 4 **reg_gpio_pd**

0x2100000f								0x2100000e								0x2100000d								0x2100000c								address
(undefined, reads zero)																GPIO pin pull-down (inverted)																value
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

Bit 0 corresponds to the GPIO channel pull-down state.

Bit value 1 indicates pullup is active; 0 indicates pulldown is inactive.

GPIO description, continued.

Table 5 **reg_pll_out_dest**

0x2f000003								0x2f000002								0x2f000001								0x2f000000								address value bit
(undefined, reads zero)																PLL clock dest.																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	

The low bit of this register directs the output of the core clock to the GPIO channel, according to the following table:

Register byte 0x2f000000 value		Clock output directed to this channel
0	0	(none)
1	1	Core PLL clock to GPIO out

Note that a high rate core clock (e.g., 80MHz) may be unable to generate a full swing on the GPIO outputs.

Table 6 **reg_trap_out_dest**

0x2f000007							0x2f000006							0x2f000005							0x2f000004							address value bit							
(undefined, reads zero)																													trap signal dest.						
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4		3	2	1	0			

The low bit of this register directs the output of the processor trap signal to the GPIO channel, according to the following table:

Register byte 0x2f000004 value		Trap signal output directed to this channel
0	0	(none)
1	1	GPIO

Table 7 **reg_irq7_source**

0x2f00000b								0x2f00000a								0x2f000009								0x2f000008								address
(undefined, reads zero)																IRQ 7 source								value								
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

The low bit of this register directs the input of the GPIO to the processor's IRQ7 channel, according to the following table:

Register byte 0x2f000008 value		This channel directed to IRQ channel 7
0	00	(none)
1	01	GPIO

Housekeeping SPI

SDI (pin F8), CSB (pin E7), SCK (pin F7), and SDO (pin E8)

The “housekeeping” SPI is an SPI slave that can be accessed from a remote host through a standard 4-pin serial interface. The SPI implementation is mode 0, with new data on SDI captured on the SCK rising edge, and output data presented on the falling edge of SCK (to be sampled on the next SCK rising edge). The SPI pins are shared with user area general-purpose I/O.

SPI protocol definition

All input is in groups of 8 bits. Each byte is input msb first.

Every command sequence requires one command word (8 bits) followed by one address word (8 bits) followed by one or more data words (8 bits each), according to the data transfer modes defined below.

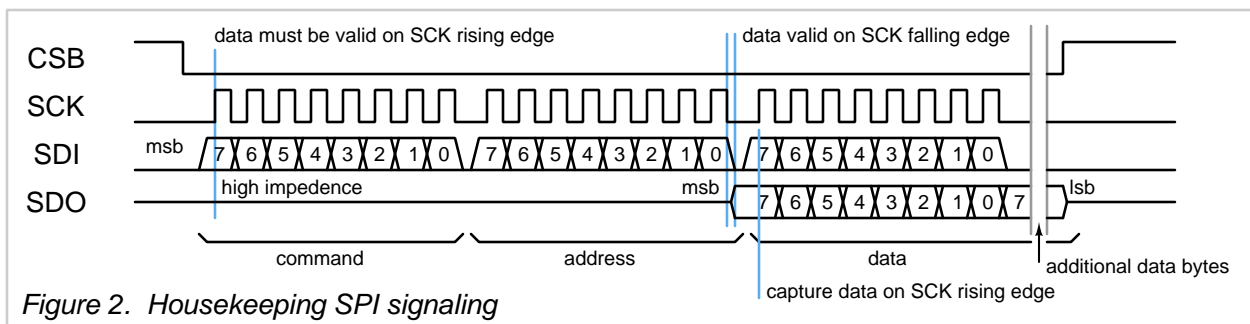

Figure 2. Housekeeping SPI signaling

Addresses are read in sequence from lower values to higher values.

Therefore groups of bits larger than 8 should be grouped such that the lowest bits are at the highest address. Any bits additional to an 8-bit boundary should be at the lowest address.

Data are captured from the register map in bytes on the falling edge of the last SCK before a data byte transfer. Multi-byte transfers should ensure that data do not change between byte reads.

CSB pin must be low to enable an SPI transmission. Data are clocked by pin SCK, with data valid on the rising edge of SCK. Output data are received on the SDO line. SDO is held high-impedance when CSB is high and at all times other than the transfer of data bits on a read command. SDO outputs become active on the falling edge of SCK, such that data are written and read on the same SCK rising edge.

After CSB is set low, the SPI is always in the "command" state, awaiting a new command.

The first transferred byte is the command word, interpreted according to Table 8 below.

Table 8 Housekeeping SPI command word definition

00000000	No operation
10000000	Write in streaming mode
01000000	Read in streaming mode
11000000	Simultaneous Read/Write in streaming mode
11000100	Pass-through (management) Read/Write in streaming mode
11000110	Pass-through (user) Read/Write in streaming mode
10nnn000	Write in n-byte mode (up to 7 bytes).
01nnn000	Read in n-byte mode (up to 7 bytes).
11nnn000	Simultaneous Read/Write in n-byte mode (up to 7 bytes).

All other words are reserved and act as no-operation if not defined by the SPI slave module.

SPI protocol definition (continued)

The two basic modes of operation are "streaming mode" and "n-byte mode". In "streaming mode" operation, data are sent or received continuously, one byte at a time, with the internal address incrementing for each byte. Streaming mode operation continues until CSB is raised to end the transfer.

In "n-byte mode" operation, the number of bytes to be read and/or written is encoded in the command word, and may have a value from 1 to 7 (note that a value of zero implies streaming mode). After n bytes have been read and/or written, the SPI returns to waiting for the next command. No toggling of CSB is required to end the command or to initiate the following command.

Pass-thru mode

The pass-thru mode puts the CPU into immediate reset, then sets FLASH_CSB low to initiate a data transfer to the QSPI flash. After the pass-thru command byte has been issued, all subsequent SPI signaling on SDI and SCK are applied directly to the QSPI flash (pins FLASH_IO0 and FLASH_CLK, respectively), and the QSPI flash data output (pin FLASH_IO1) is applied directly to SDO, until the CSB pin is raised. When CSB is raised, the FLASH_CSB is also raised, terminating the data transfer to the QSPI flash. The CPU is brought out of reset, and starts executing instructions at the program start address.

This mode allows the QSPI flash to be programmed from the same SPI communication channel as the housekeeping SPI, without the need for additional wiring to the QSPI flash chip.

There are two pass-thru modes. The first one corresponds to the primary SPI flash used by the management SoC. The second one corresponds to a secondary optional SPI flash that can be defined in the user project. The pass-thru mode allows a communications chip external to the Caravel chip program either SPI flash chip from a host computer without requiring separate external access to the SPI flash. Both pass-thru modes only connect to I/O pins 0 and 1 of the SPI flash chips, and so must operate only in the 4-pin SPI mode. The user project may elect to operate the SPI flash in quad mode using a 6-pin interface.

Housekeeping SPI registers

The purpose of the housekeeping SPI is to give access to certain system values and controls independently of the CPU. The housekeeping SPI can be accessed even when the CPU is in full reset. Some control registers in the housekeeping SPI affect the behavior of the CPU in a way that potentially can be detrimental to the CPU operation, such as adjusting the trim value of the digital frequency-locked loop generating the CPU core clock.

Under normal working conditions, the SPI should not need to be accessed unless it is to adjust the clock speed of the CPU. All other functions are purely for test and debug.

The housekeeping SPI can be accessed by the CPU from a running program by enabling the SPI master, and enabling the bit that connects the internal SPI master directly to the housekeeping SPI. This configuration then allows a program to read, for example, the user project ID of the chip. See the SPI master description for details.

manufacturer_ID register address 0x01 low 4 bits and register address 0x02
The 12-bit manufacturer ID for efabless is 0x456

product_ID register address 0x03
The product ID for the Caravel harness chip is 0x10

Housekeeping SPI registers (continued)

user project ID register addresses 0x04 to 0x07

The 4-byte (32 bit) user project ID is metal-mask programmed on each project before tapeout, with a unique number given to each user project.

PLL enable register address 0x08 bit 0

This bit enables the digital frequency-locked-loop clock multiplier. The enable should be applied prior to turning off the PLL bypass to allow the PLL time to stabilize before using it to drive the CPU clock.

PLL DCO enable register address 0x08 bit 1

The PLL can be run in DCO mode, in which the feedback loop to the driving clock is removed, and the system operates in free-running mode, driven by the ring oscillator which can be tuned between approximately 90 to 200 MHz by setting the trim bits (see below).

PLL bypass register address 0x09 bit 0

When enabled, the PLL bypass switches the clock source of the CPU from the PLL output to the external CMOS clock (pin C9). The default value is 0x1 (CPU clock source is the external CMOS clock).

CPU IRQ register address 0x0A bit 0

This is a dedicated manual interrupt driving the CPU IRQ channel 6. The bit is not self-resetting, so while the rising edge will trigger an interrupt, the signal must be manually set to zero before it can trigger another interrupt.

CPU reset register address 0x0B bit 0

The CPU reset bit puts the entire CPU into a reset state. This bit is not self-resetting and must be set back to zero manually to clear the reset state.

CPU trap register address 0x0C bit 0

If the CPU has stopped after encountering an error, it will raise the trap signal. The trap signal can be configured to be read from a GPIO pin, but as the GPIO state is potentially unknowable, the housekeeping SPI can be used to determine the true trap state.

PLL trim register addresses 0x0D (all bits) to 0x10 (lower 2 bits)

The 26-bit trim value can adjust the DCO frequency over a factor of about two from the slowest (trim value 0x3ffffff) to the fastest (trim value 0x0). Default value is 0x3ffefff (slow trim, -1).

Note that this is a thermometer-code trim, where each bit provides an additional (approximately) 250 ps delay (on top of a fixed delay of 4.67 ns). The fastest output frequency is approximately 215 MHz while the slowest output frequency is approximately 90 MHz.

PLL output divider register address 0x11 bits 2–0

The PLL output can be divided down by an integer divider to provide the core clock frequency. This 3-bit divider can generate a clock divided by 2 to 7. Values 0 and 1 both pass the undivided PLL clock directly to the core (and should not be used, as the processor does not operate at these frequencies).

PLL output divider (2) register address 0x11 bit 5–3

The PLL 90-degree phase output is passed through an independent 3-bit integer clock divider and provided to the user project space as a secondary clock. Values 0 and 1 both pass the undivided PLL clock, while values 2 to 7 pass the clock divided by 2 to 7, respectively.

Housekeeping SPI registers (continued)**PLL feedback divider** register address 0x12 bits 4–0

The PLL operates by comparing the input clock (pin C9) rate to the rate of the PLL clock divided by the feedback divider value (when running in PLL mode, not DCO mode). The feedback divider must be set such that the external clock rate multiplied by the feedback divider value falls between 90 and 214 MHz (preferably centered on this range, or approximately 150 MHz). For example, when using an 8 MHz external clock, the divider should be set to 19 ($19 * 8 = 152$). The DCO range and the number of bits of the feedback divider implies that the external clock should be no slower than around 4 to 5 MHz.

Table 9 Housekeeping SPI register map

Register Address	msb								lsb	
	7	6	5	4	3	2	1	0	comments	
0x00	SPI status and control								unused/ undefined	
0x01	unused				manufacturer_ID[11:8] (= 0x4)				read-only	
0x02	manufacturer_ID[7:0] (= 0x56)								read-only	
0x03	product_ID (= 0x10)								read-only	
0x04– 0x07	user_project_ID (unique value per project)								read-only	
0x08	unused						PLL DCO enable	PLL enable	default 0x02	
0x09	unused							PLL bypass	default 0x01	
0x0A	unused							CPU IRQ	default 0x00	
0x0B	unused							CPU reset	default 0x00	
0x0C	unused							CPU trap	read-only	
0x0D– 0x10	DCO trim (26 bits) (= 0x3fffff)								default 0x3fffff	
0x11	unused		PLL output divider 2			PLL output divider			default 0x12	
0x12	unused			PLL feedback divider					default 0x04	

QSPI Flash interface

flash io0–1 (pins D9 to D10), flash csb (pin C10), and flash clk (pin C8)

The QSPI flash controller is automatically enabled on power-up, and will immediately initiate a read sequence in single-bit mode with pin "flash io0" acting as SDI (data from flash to CPU) and pin "flash io1" acting as SDO (data from CPU to flash). Protocol is according to, e.g., Cypress S25FL256L.

The initial SPI instruction sequence is as follows:

0xFF Mode bit reset
0xAB Release from deep power-down
0x03 Read w/3 byte address
0x00 Program start address (**0x10000000**) (3 bytes) (upper byte is ignored)
0x00
0x00

The QSPI flash continues to read bytes, either sequentially on the same command, or issuing a new read command to read from a new address.

The behavior of the QSPI flash controller can be modified by changing values in the register below:

Table 10

reg_spictrl

0x2d000003										0x2d000002										0x2d000001										0x2d000000										address value bit
(unused)										(see below)										(unused)										(see below)										
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0									

mask bit	default	description
31	1	QSPI flash interface enable
22–20	0	Access mode (see table below)
19–16	8	Dummy clock cycle count
11–8	0	Bit-bang OE FLASH_IO3–FLASH_IO0
5	0	Bit-bang FLASH_CSB
4	0	Bit-bang FLASH_CLK
3–0	0	Bit-bang value FLASH_IO3–FLASH_IO0

Access mode bit selection (bits 22–20):

0	000	Single bit per clock
1	001	Single bit per clock (same as 0)

All additional modes (QSPI dual and quad modes) cannot be used, as the management SoC only has pins for data lines 0 and 1.

The SPI flash can be accessed by bit banging when the enable is off. To do this from the CPU, the entire routine to access the SPI flash must be read into SRAM and executed from the SRAM.

Interrupt

IRQ (pin E5)

The interrupt pin triggers the CPU interrupt channel 5.

External clock clock (pin C9)

The external clock functions as the source clock for the entire processor. On start-up, the processor runs at the same rate as the external clock. The processor program may access the housekeeping SPI to set the processor into PLL mode or DCO free-running mode. In PLL mode, the external clock is multiplied up by the feedback divider value to obtain the core clock. In DCO mode, the processor is driven by a trimmed free-running ring oscillator.

UART ser tx (pin E6) and ser rx (pin F6)

The UART is a standard 2-pin serial interface that can communicate with most similar interfaces at a fixed baud rate. Although the UART operates independently of the CPU, data transfers are blocking operations which will generate CPU wait states until the data transfer is completed.

The behavior of the UART can be modified by changing values in the registers below:

Table 11 **reg_uart_clkdiv**

0x20000003								0x20000002								0x20000001								0x20000000								address
UART clock divider																																value
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

The entire 32 bit word encodes the number of CPU core cycles to divide down to get the UART data bit rate (baud rate). The default value is 1.

Example: If the external crystal is 12.5MHz, then the core CPU clock runs at 100MHz. To get 9600 baud, $100E6 / 9600 = 10417$ (hex value 0x28b1).

Table 12 **reg_uart_data**

0x20000007								0x20000006								0x20000005								0x20000004								address								
(unused, value is 0x0)																																								value
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit								

Writing a value to this register will immediately start a data transfer on the SER_TX pin. If a UART write operation is pending, then the CPU will be blocked with wait states until the transfer is complete before starting the new write operation. This makes the UART transmit a relatively expensive operation on the CPU, but avoids the necessity of buffering data and checking for buffer overflow. Reading a value from this register returns 255 (0xff) if no valid data byte is in the receive buffer, and returns the value of the receive buffer otherwise, and clears the receive buffer for additional reads. Note that there is no FIFO associated with the UART.

Table 13 **reg_uart_enable**

0x2000000b								0x2000000a								0x20000009								0x20000008								address
(unused, value is 0x0)																								value								
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

The UART must be enabled to run (default disabled)

SPI Master spi sdi (pin E8), spi csb (pin E7), spi sck (pin F7), and spi sdo (pin F8)

Table 14 **reg_spi_config**

0x24000003								0x24000002								0x24000001								0x24000000								address
(undefined, reads zero)																SPI master configuration																value
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

Configuration bit definitions

Bit 15	Housekeeping	0 = SPI master connected to external pins 1 = SPI master connected directly to housekeeping SPI
Bit 14	SPI interrupt enable	0 = interrupt disabled 1 = interrupt enabled
Bit 13	SPI system enable	0 = SPI disabled 1 = SPI enabled
Bit 12	stream	0 = apply/release CSB separately for each byte 1 = apply CSB until stream bit is cleared (manually)
Bit 11	mode	0 = read and change data on opposite SCK edges 1 = read and change data on the same SCK edge
Bit 10	invert SCK	0 = normal SCK 1 = inverted SCK
Bit 9	invert CSB	0 = normal CSB (low is active) 1 = inverted CSB (high is active)
Bit 8	MLB	0 = msb first 1 = lsb first
Bits 7–0	prescaler	count (in master clock cycles) of 1/2 SCK cycle (default value 2)

All configuration bits other than the prescaler default to value zero.

Table 15 **reg_spi_data**

0x24000007								0x24000006								0x24000005								0x24000004								address value bit
(undefined, reads zero)																SPI data																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	

The byte at 0x24000004 holds the SPI data (either read or write)

Reading to and writing from the SPI master is simply a matter of setting the required values in the configuration register, and writing values to or reading from reg_spi_data. The protocol is similar to the UART. A write operation will stall the CPU if an incomplete SPI transmission is still in progress. Reading from the SPI will also stall the CPU if an incomplete SPI transmission is still in progress. There is no FIFO buffer for data. Therefore SPI reads and writes are relatively expensive operations that tie up the CPU, but will not lose or overwrite data. Note that there is no FIFO associated with the SPI master.

Counter-Timer 0

The counter/timer is a general-purpose 32-bit adder and subtractor that can be configured for a variety of timing functions including one-shot counts, continuous timing, and interval interrupts. At a core clock rate of 80MHz, the longest single time interval is 26.84 seconds.

Table 16 **reg_timer0_config**

0x22000003								0x22000002								0x22000001								0x22000000								address
(undefined, reads zero)																								Timer config								value
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

Timer configuration bit definitions

Bit 3	Counter/timer enable	1 = counter/timer enabled 0 = counter/timer disabled
Bit 2	Oneshot mode	1 = oneshot mode 0 = continuous mode
Bit 1	Updown	1 = count up 0 = count down
Bit 0	Interrupt enable	1 = interrupt enabled 0 = interrupt disabled

Table 17 **reg_timer0_value**

0x22000007				0x22000006				0x22000005				0x22000004				address																
Timer value																value																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

The value in this register is the current value of the counter. Value is 32 bits. The register is read-write and can be used to reset the timer.

Table 18 **reg_timer0_data**

0x2200000b				0x2200000a				0x22000009				0x22000008				address																
Timer data																value																
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

The value in this register is the reset value for the comparator.

When enabled, the counter counts up or down from the value set in reg_timer_value at the time the counter is enabled. If counting up, the count continues until the counter reaches reg_timer_data. If counting down, the count continues until the counter reaches zero.

In continuous mode, the counter resets to zero if counting up, and resets to the value in reg_timer_data if counting down, and the count continues immediately. If the interrupt is enabled, the counter will generate an interrupt on every cycle.

In one-shot mode, the counter triggers an interrupt (IRQ channel 10; see next page) when it reaches the value of reg_timer_data (up count) or zero (down count), and stops.

Note: When the counter/timer is disabled, the reg_timer_value remains unchanged, which puts the timer in a hold state. When re-enabled, counting resumes. To reset the timer, write zero to the reg_timer_value register.

Counter-Timer 1

The second counter/timer is functionally identical to the first, with different memory mapped addresses for the controls, as shown in the tables below.

Table 19

reg_timer1_config

0x23000003								0x23000002								0x23000001								0x23000000								address
(undefined, reads zero)																								Timer config								value
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

Timer configuration bit definitions

Bit 3	Counter/timer enable	1 = counter/timer enabled 0 = counter/timer disabled
Bit 2	Oneshot mode	1 = oneshot mode 0 = continuous mode
Bit 1	Updown	1 = count up 0 = count down
Bit 0	Interrupt enable	1 = interrupt enabled 0 = interrupt disabled

Table 20

reg_timer1_value

0x23000007								0x23000006								0x23000005								0x23000004								address
Timer value																																value
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

The value in this register is the current value of the counter. Value is 32 bits. The register is read-write and can be used to reset the timer.

Table 21

reg_timer1_data

0x2300000b								0x2300000a								0x23000009								0x23000008								address
Timer data																																value
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	bit

The value in this register is the reset value for the comparator.

When enabled, the counter counts up or down from the value set in reg_timer_value at the time the counter is enabled. If counting up, the count continues until the counter reaches reg_timer_data. If counting down, the count continues until the counter reaches zero.

In continuous mode, the counter resets to zero if counting up, and resets to the value in reg_timer_data if counting down, and the count continues immediately. If the interrupt is enabled, the counter will generate an interrupt on every cycle.

In one-shot mode, the counter triggers an interrupt (IRQ channel 11; see next page) when it reaches the value of reg_timer_data (up count) or zero (down count), and stops.

Note: When the counter/timer is disabled, the reg_timer_value remains unchanged, which puts the timer in a hold state. When re-enabled, counting resumes. To reset the timer, write zero to the reg_timer_value register.

Interrupts (IRQ)

The interrupt vector is set to memory address 0 (bottom of SRAM). The program counter switches to this location when an interrupt is received. To enable interrupts, it is necessary to copy an interrupt handler to memory location 0. The PicoRV32 defines 32 IRQ channels, of which the Caravel chip uses only a handful, as described in the table below. All IRQ channels not in the list below always have value zero.

Table 19 CPU IRQ channel definitions

<i>IRQ channel</i>	<i>description</i>
4	UART data available
5	IRQ external pin (pin E5)
6	Housekeeping SPI IRQ
7	Assignable interrupt (see Table 7)
9	SPI master data available, when enabled (see Table 14)
10	Timer 0 expired, when enabled (see Table 16)
11	Timer 1 expired, when enabled (see Table 19)

The Caravel PicoRV32 implementation does not enable IRQ QREGS (see PicoRV32 description).

The handling of interrupts is beyond the scope of this document (see RISC-V instruction set description). All interrupts are masked and must be enabled in software.

Management area SRAM

The Caravel chip has an on-board memory of 1024 words of width 32 bits. The memory is located at address 0 (zero).

Storage area SRAM

The Caravel chip has a “storage area” SRAM block that is auxiliary space that can be used by either the management SoC or the user project, through the wishbone bus interface. The storage area is connected into the user area 2 power supply, and so is nominally considered to be part of the user area.

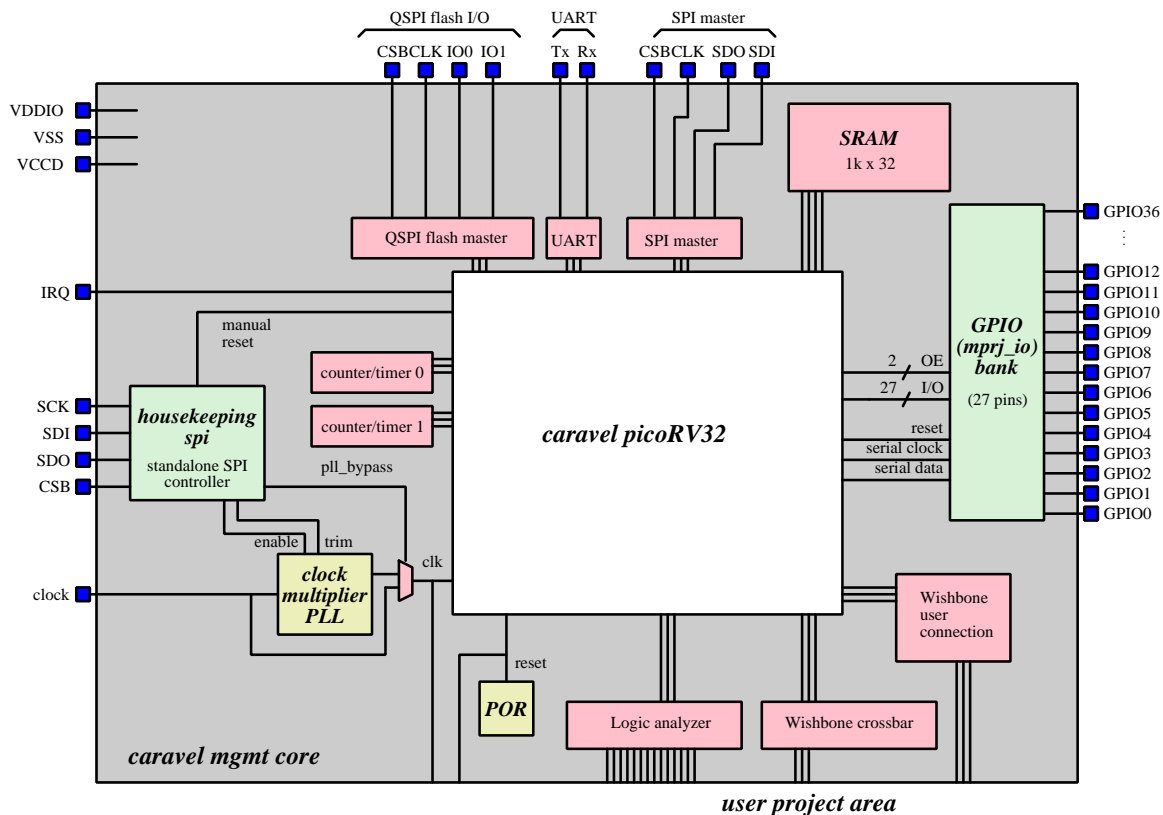

The storage area may be used as an experimentation area for OpenRAM, so for any user project making use of this space, the user should notify efabless of their requirement for the size and configuration of the SRAM block.

Programming

The RISC-V architecture has a **gcc** compiler. The best reference for getting the correct cross-compiler version is the PicoRV32 source at

<http://github.com/cliffordwolf/picorv32>.

Specifically, see the top-level **README.md** file section “Building a pure RV32I Toolchain.”

For programming examples specifically for the Caravel chip (assuming a correct installation of a RISC-V gcc toolchain as described above), see

<http://github.com/efabless/caravel>

The directory **verilog/dv** contains example source code to program the Ravenna chip along with the header file **defs.h** that defines the memory-mapped locations as described throughout this text.

The **verilog/dv** directory contains a **Makefile** that compiles hex files and runs simulations of a number of test programs that exercise various features of the chip.

Additional documentation exists on the same site for the provided demonstration circuit board and driver software.
